19. ABSTRACT (Continue on reverse if necessary and identify by block number) All new tactical vehicles and aircraft are required to be evaluated for potential whole-body vibration (WBV) health hazards to their crewmembers. A health hazard assessment (HHA) was performed on the M915A2 truck tractor by the U.S. Army Aeromedical Research Laboratory, as requested by the U.S. Army Environmental Hygiene Agency. Tests were conducted at Aberdeen Proving Ground, Maryland, over paved surface, cross-country, and Belgian Block terrain types. The M915A2 was tested in bobtail (no trailer), unloaded, and loaded configurations for each of the test terrains. The results of these tests show the lowest tolerance levels, in general, were experienced on the cross-country course, with less severe WBV occurring on the Belgian Block course, followed by the primary terrain course.

19. (Continued)

The HHA recommendation for the M915A2, operating in its intended environment, is that WBV be limited to the following exposure limits for each test condition: WBV is not to exceed 8.97, 17.19, and 18 hours in any 24-hour period on paved surfaces for the bobtail, unloaded, and loaded configurations, respectively, for speeds up to 45 mph. Exposure limits for the cross-country terrain, for speeds up to 12 mph, are 8.56, 17.19, and 10.28 hours in any 24-hour period for the bobtail, unloaded, and loaded configurations, respectively. For the Belgian block terrain, WBV in any 24-hour period should not exceed 9.88, 14.56, and 17.09 hours for the bobtail, unloaded and loaded configurations, respectively, for speeds up to 25 mph.

Acknowledgments

The authors would like to express their gratitude to Dr. Nabih Alem for his efforts in developing software for the data analysis. Michael Deavers is acknowledged for his assistance with data analysis and editing. Mrs. Mary Gramling and Mr. Udo Nowak also are commended for their efforts in editing this report.

Introduction

All new tactical vehicles and aircraft are required to be evaluated for potential whole-body vibration (WBV) health hazards to their crewmembers. This requirement is contained in AR 40-10, "Health hazard assessment program in support of the Army materiel acquisition decision process." In support of this program, the U.S. Army Aeromedical Research Laboratory (USAARL) was requested by the U.S. Army Environmental Hygiene Agency (USAEHA) to perform a Health Hazard Assessment (HHA) on the M915A2 truck tractor.

The M915A2 truck tractor* (hereafter referred to as "M915A2") is a 14 ton, 6 x 4 commercially designed truck tractor built by Freightliner Corporation* (Figure 1). It is powered by a Detroit Diesel DDE engine* which develops 400 hp at 2100 rpm. The transmission is a Detroit Diesel Allison HT 740 CR automatic* with 4 forward gears and one reverse gear. The M915A2 is intended for use with the M871 (22-ton) and M872 (34-ton) flatbed semitrailers, and the M1062 7500-gallon fuel tanker. The M915A2 primarily will be used in the Communications Zone (COMMZ) over primary and secondary roads and, occasionally, on off-road terrain. These vehicle configurations are considered when designing the test matrix for measuring the WBV signatures.

The methods for measuring and analyzing WBV are found in the International Organization for Standardization's (ISO) guideline entitled "Guide for the evaluation of human exposure to whole-body vibration (ISO 2631)." ISO 2631 is reflected in MIL-STD-1472D, "Human engineering design criteria for military systems, equipment and facilities." The relative severity of the processed WBV signatures are interpreted using the Risk Assessment Codes (RAC) found in AR 40-10. These publications as a set define the criteria used in evaluating the WBV signatures of the M915A2.

ISO 2631 identifies three criteria for the evaluation of human exposure to WBV which can be described in terms of intensity, frequency, direction, and duration. These criteria are the preservation of comfort, the preservation of working efficiency, and the preservation of health or safety. They are known formally as the reduced comfort boundary (RCB), fatigue-decreased proficiency boundary (FDPB), and the exposure limit (EL), respectively.

* See list of manufacturers.

Figure 1. M915A2 truck tractor.

The RACs, as described in AR 40-10, Appendix B, require the classification of a health hazard according to its severity and probability. Processing vibration signatures using ISO-2631 results in measurements of vibration severity, but does not yield a measure of the probability of occurrence. RACs are obtained by combining vibration severity with the probability that the test condition will occur in a real life scenario. For vibration, RACs would be determined for each vibration amplitude at each direction and frequency.

Methods

Whole-body vibration data for the M915A2 was collected at Aberdeen Proving Ground (APG), Maryland, by the U.S. Army Combat Systems Test Activity (USACSTA) in coordination with the Response and Tolerance Branch of USAARL. A test matrix was developed that represented the planned operating environment of the M915A2 with respect to terrain type, load configuration, and vehicle speed (Table 1).

Table 1.

Test matrix for WBV testing of the M915A2.

Vehicle speed(m.p.h.)	Terrain

15			X
20			X
25			X
35	X		
45	X		
55	X		

* Each configuration shown was tested for the loaded, unloaded, and bobtail load cases.

Experimental conditions

The M915A2 was tested under three terrain conditions: primary, cross-country, and Belgian block. The primary surface was a 3-mile, smooth, level, straight, asphalt test track. The cross-country surface was a rough dirt road with numerous potholes and uneven ruts. It had been used recently for the testing of track vehicles. The Belgian block was an oval cobblestone road approximately $\frac{1}{2}$ -mile long with an irregular pattern of 3-inch crests. These crests were spaced such that there was no correlation between the locations of the crests for the right and left wheel track. All three courses are part of the APG test track facilities. Characterizations of these surfaces are available from APG.

The M915A2 was tested under three load conditions: bobtail, unloaded, and loaded configuration. The bobtail configuration consisted of the tractor without the trailer attached. The unloaded configuration consisted of the tractor with an empty 22-ton M871 low-bed semitrailer attached. The loaded configuration

consisted of the tractor with the M871 trailer attached and with a load of 44,000 lbs.

The M915A2 was tested using vehicle speeds ranging from 8 to 55 m.p.h. Specific vehicle speed selection depended on the test terrain and mirrored likely employment scenarios. On the paved course, the M915A2 was tested at three speeds: 35, 45, and 55 m.p.h. On the cross-country course, it was tested at 8, 10, and 12 m.p.h. And on the Belgian block course it was tested at three speeds: 15, 20, and 25 m.p.h.

The test matrix consisted of combinations of terrain surface, load configuration, and vehicle speed, which resulted in a total of 27 vehicle runs. Seat pad accelerations were collected from the instrumented driver and passenger seat for each of the X- (fore/aft), Y- (left/right), and Z- (up/down) axes. Combinations of vehicle test runs with vibration axes yielded 162 distinct data trials.

The seats in the M915A2 were adjusted so the distance from the floor to the underside of the seat frame was 11 inches. This corresponds to a seat height at approximately one-half the possible stroke. The driver was 5'10" tall and weighed 156 lbs. The passenger was 6'3" tall and weighed 192 lbs.

Instrumentation

Seat pad accelerations were obtained in the X-, Y-, and Z-axes for both the driver and passenger seats. Three Endevco model 2265C-25 accelerometers*, in a triaxial arrangement, were attached to a disk placed between the seat pad and the subjects' buttocks. Each of the accelerometers were connected to a signal conditioner which provided excitation, amplification, calibration, and low-pass filtering. The accelerometers were low-pass filtered at 100 Hz using a six-pole Butterworth filter. A diagram of the data acquisition system is included as Figure 2.

Filtered acceleration signals from the signal conditioner were connected to an EMR Model 372-03 pulse code modulation (PCM) encoder*. The encoder multiplexed the incoming analog signals which then were sampled at 416.67 Hz per channel. The incoming analog signal was sampled using a sample-and-hold amplifier, digitized using a 10-bit successive approximation analog-to-digital converter, and then converted to a nonreturn-to-zero level (NRZ-L) code for transmission. The encoded PCM data then was input to a Conic model CTL 510 transmitter* for transmission at 237 MHz to the remote data handling facility. The signal conditioner, encoder, and transmitter were mounted on the back of the M915A2 cab during the entire test.

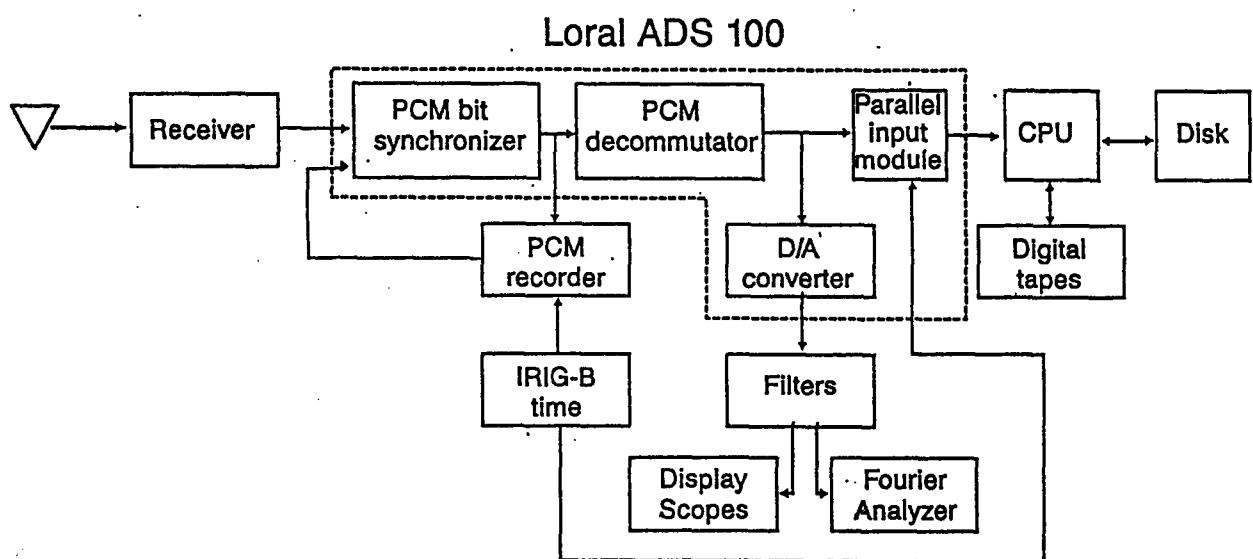

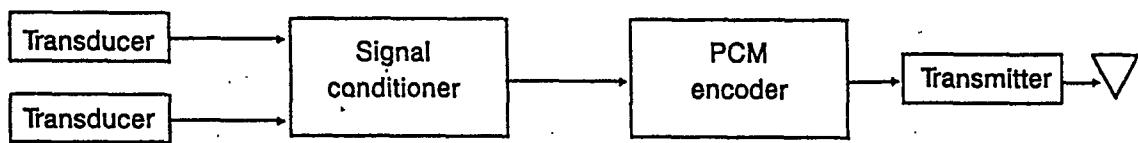

Figure 2. Data acquisition system.

The transmitted NRZ-L code was received by a Scientific Atlanta series 420S receiver* and passed into a Loral Instrumentation ADS-100 system*. The input buffer and PCM bit synchronizer modules recovered the serial pulse train from the data link noise and disturbances. The pulse was recorded on a Honeywell model 101 PCM tape recorder* along with voice annotation of the individual test runs and IRIG-B time code. Simultaneously, the PCM pulse train was passed to a PCM decommutator and demultiplexed into 16-bit words.

From this point, the pulse train was sent to both a digital-to-analog (D/A) converter and a parallel input module. The D/A converter passed the pulse train through a filter, external to the ADS-100 system, for real time display and fourier analysis. The parallel input module was used to input digital IRIG-B time code into the ADS-100. The pulse train passed out of the ADS-100 system from the input module to the host computer--a Hewlett Packard model 21MX-E series minicomputer*. The data were stored temporarily on the HP system disk and later transferred to digital tape to provide a permanent storage medium. The ADS-100 system was independent of the host control; however, software residing on the minicomputer controlled the hand shaking between the ADS-100 and the HP21MX-E during data acquisition.

Analysis

Triaxial seat pad vibration data were processed using the methods prescribed in ISO 2631 for broadband signals using third-octave analysis with weighting. Digitized acceleration signals from the X-, Y-, and Z-axes, from both the driver and passenger seat pad accelerometers, were read into a Dolch model 486 portable computer*. A USAARL-developed automated analysis program was used to produce tabular and graphic plots of the acceleration data. These plots (Appendix B) were used to identify vibration exposure limits which occurred under projected normal daily operating conditions.

The RACs require classification of the health hazard according to the hazard severity and probability. Since the ISO 2631 standard does not use RACs directly, the severity of the hazard may be estimated reasonably from the worst-case exposure before the onset of ELs (i.e., for any vibration frequency and direction). An indicator which may be used for the assessment of hazard severity is the duration of safe exposure (DSE). The DSE is defined as the length of time a person can be exposed to WBV before reaching the health and safety exposure limit (HSEL). Thus, a long DSE indicates tolerable WBV, whereas a short DSE indicates severe WBV. In order to translate the DSEs to hazard severity, Table 2 was used to define the category (I-IV) of exposure.

Table 2.

Hazard severity classification.

Attribute	Category	Duration of safe exposure (DSE) to WBV
Catastrophic	I	Less than 5 minutes
Critical	II	Between 5 and 30 minutes
Marginal	III	Between 30 minutes and 4 hours
Negligible	IV	More than 4 hours

Hazard severity categories are defined as follows:

Category I - Catastrophic: Hazard may cause death or total loss of a bodily system.

Category II - Critical: Hazard may cause severe bodily injury, severe occupational illness, or major damage to a bodily system.

Category III - Marginal: Hazard may cause minor bodily injury, minor occupational illness, or minor damage to a bodily system.

Category IV - Negligible: Hazard would cause less than minor bodily injury, minor occupational illness, or minor bodily system damage.

The operational environments of the M915A2 determine the likelihood of occurrence, or hazard probability level, of exposure to WBV. These levels, identified as levels A through E in AR 40-10, with their corresponding operating conditions relevant to the WBV signatures in the M915A2, are listed in Table 3.

Operating the M915A2 over paved surfaces represents approximately 75 percent of the total mission, therefore, the probability of WBV exposure over similar courses is frequent and may be assigned hazard probability level A. The operation over cross-country roads is assigned a Hazard Probability Level B, which represents approximately 20 percent of its mission time. Operating over unimproved secondary roads, represented by the Belgian block, is within the M915A2 mission, but its occurrence should be only occasional, prompting the assignment of hazard probability level C to this course.

Table 3.
Hazard probability classification.

Attribute	Level	Road/terrain type, operating speed
Frequent	A	Primary roads, 40-65 m.p.h. Cross-country, 8 m.p.h. and under
Probable	B	Primary roads, 20-40 m.p.h. Cross-country, 9-16 m.p.h.
Occasional	C	Belgian block, 5-15 m.p.h.
Remote	D	Belgian block, above 15 m.p.h.
Improbable	E	Conditions unlikely to occur

Hazard severity categories and levels are used to find the RACs for each test condition. Using Table 4, the RACs are found at the intersection of the category and level. Overall RAC for the vehicle then is determined by weighting the individual test RACs according to the percent of mission time the run represented and then averaging and rounding to a final RAC.

Table 4.
RAC determination.

Hazard category	Hazard probability levels				
	A	B	C	D	E
I	1	1	1	2	3
II	1	1	2	3	4
III	2	3	3	4	5
IV	3	5	5	5	5

Results

The duration of exposure (in hours) necessary to reach the HSEL was calculated for all 54 data sets. Since the M915A2 mission requires 10 hours of operation over primary, secondary, and cross-country terrain, the exposure times of less than 10 hours were flagged for assessment and are listed in Table 5.

The DSEs for passenger and driver ranged from a low of 6.31 hours to a high of 35.69 hours. For speeds up to 45 mph, exposure limits for the primary surface indicate that WBV exposures in any 24-hour period be limited to 18 hours for the loaded configuration, 8.97 hours for the bobtail configuration and 22 hours for the unloaded configuration. It should be noted here that tests on the primary terrain at 55 mph resulted in a considerable increase in vibration, and exposure at this speed should be limited to 6.31 hours. Exposure limits for the cross-country terrain indicate WBV exposure be limited to 10.28, 8.56, and 17.19 hours for the loaded, bobtail, and unloaded configurations, respectively, for speeds ranging from 8 to 12 mph. Exposure limits for the Belgian block surface for speeds ranging from 15 to 25 mph indicate WBV exposure be limited to 17.09, 9.88, and 14.56 hours for the loaded, bobtail, and unloaded configurations, respectively.

The frequencies at which the HSELs were reached fell in the range from 2.2 to 7.1 Hz for both passenger and driver. The majority of the HSELs occurred at frequency levels in the range of 4.5 to 7.1 Hz, which lies in the WBV resonance frequency range (4 to 8 Hz).

Because the DSEs were well above the 4-hour mark as defined in Table 2, hazard severity was determined to be negligible for all the data sets for both passenger and driver. This resulted in RAC categories of 4 for both positions. RAC exposure probability included remote, occasional, probable, and frequent for the passenger and driver. Overall RACs were 3 and 5 for both positions. The single RAC for the M915A2 was determined by weighting the individual RACs according to their percentage of total mission time and then averaging and rounding to a final RAC. The overall RAC for the M915A2 truck was calculated to be 4.

Discussion

For the worst case on each test course, the lowest tolerance levels were experienced on the primary surface (6.31 hours, run 026, 55 mph), with less severe WBV occurring on the Belgian block course (9.88 hours, run 008), followed by the cross-country course (8.56 hours, run 010). However, the general trend of the

Table 5.

Seat HSEL for times of less than 10 hours with respect to Z-axis, vibration frequency, vehicle speed, terrain surface, and vehicle load.

Determination of RAC categories					Determination of RAC levels					Over-all RAC
DSE hours	Hz	Seat position	Hazard severity	RAC category	Test course	Config-uration	Speed (MPH)	Exposure proba-bility	RAC level	
6.31	7.1	Passenger	Negligible	IV	Primary	Loaded	55	Frequent	A	3
8.56	7.1	Driver	Negligible	IV	Cross-country	Bobtail	12	Probable	B	5
8.97	5.7	Passenger	Negligible	IV	Primary	Bobtail	45	Frequent	A	3
9.88	4.5	Driver	Negligible	IV	Belgian block	Loaded	8	Occasion-al	C	5

exposure limits indicates that overall, the lowest tolerance levels were experienced on the cross-country course with DSEs ranging from 8.56 to 28.56 hours. Next, the tolerances for the Belgian block course ranged from 9.88 to 35.69 hours. Finally, the highest tolerance levels overall were experienced on the primary course with DSEs ranging from 6.31 to 36.69 hours.

The WBV experienced by the vehicle crewmen differed for seating position. The passenger position data typically showed a lower exposure limit as compared to the driver position for most of the data trials. This situation is most apparent under the Belgian block surface where vehicle roll occurred. A likely reason for this result is that the passenger does not have hand holds which can be used to dampen WBV. By grabbing the steering wheel, the driver can reduce the amount of upper body sway. This in turn lowers the amount of induced seat motion resulting in a lower apparent WBV measurement at that seating position. The addition of both right and left hand holds for the passenger would reduce the amount of vibration measured at that position and likely would improve the perceived ride quality.

Conclusion

Results from this WBV test indicate that while operating the M915A2 in its intended operational environment, both driver and passenger were exposed to an overall RAC of 4. It is recommended that exposure to WBV be restricted to the following:

1. Paved surface, up to 45 mph: Bobtail configuration, not more than 9 continuous hours in any 24-hour period.
2. Paved surface, up to 45 mph: Unloaded configuration, not more than 22 continuous hours in any 24-hour period.
3. Paved surface, up to 45 mph: Loaded configuration, not more than 18 continuous hours in any 24-hour period.
4. Cross-country terrain, up to 12 mph: Bobtail configuration, not more than 9 continuous hours in any 24-hour period.
5. Cross-country terrain, up to 12 mph: Unloaded trailer, not more than 17 continuous hours in any 24-hour period.
6. Cross-country terrain, up to 12 mph: Loaded trailer, not more than 10 continuous hours in any 24-hour period.
7. Belgian block, up to 25 mph: Bobtail configuration, not more than 10 continuous hour in any 24-hour period.

8. Belgian block, up to 25 mph: Unloaded configuration, not more than 15 continuous hours in any 24-hour period.
9. Belgian block, up to 25 mph: Loaded configuration, not more than 17 continuous hours in any 24-hour period.
